(54) Queue management system

(57) A queue management system for managing at least one queue of people comprises a plurality of portable modules, at least one docking station, a queue manager, at least one module detector and a communication means. Each portable module includes memory means for containing a unique identification code, indicator means for indicating to the person or group of people carrying the module when it is time to join the or each queue, signal receiver means for receiving signals to cause the indicator means to be operative, transmitter means for transmitting the identification code over a short range, and docking means for downloading the identification code when the portable module is docked for registering the person or group of people in queue sequence for a respective queue.

The queue manager maintains the queue sequence for the or each queue and includes a communication means for receiving the or each downloaded code and a transmitter for transmitting the signals to each portable module to instruct the person or group of people carrying the portable module to join a queue.

Description

QUEUE MANAGEMENT SYSTEM

The present invention generally relates to a queue management system for managing at least one queue of people.

In many leisure pursuits (such as theme parks and museums) and other activities (such as arranging visas and immigration procedures), a large amount of time can be spent waiting in queues. The queuing is a frustrating and unproductive use of the time of the person in the queue and can be economically inefficient for the enterprise concerned. However, significant queues are necessary for at least part of the time in order to make efficient use of the particular resource.

The problem of managing queues has been addressed in the prior art such as in EP0086199. In the system disclosed in EP0086199 a queue sequence for serving customers at a number of service points is determined once a customer has been allocated a turn number. The customer can then be told which queue to attend by observing a display.

This prior art arrangement is particularly suitable for queues such as in supermarkets wherein the queue time is generally not that long and the person will therefore accept the necessity for waiting near the queuing area and viewing the display.

However, for multiple queues at remote locations or for one or more queues which have a considerable delay associated therewith, the system does not enable the person queuing to physically leave the queue without there being a possibility of the person losing their place in the queue.

It is therefore an object of the present invention to provide a queue management system which allows people to join a "virtual" queue, thus freeing the person from having to wait near the queue.

The present invention provides a queue management system for managing at least one queue of people, the system comprising a plurality of portable modules, each portable module being arranged to be carried by a person or a group of people and including memory means for containing a unique identification code, indicator means for indicating to said person or group of people when it is time to join the or each queue, signal receiver means for receiving signals to cause said indicator means to be operative, transmitter means for transmitting said identification code over a short range to confine the transmitted identification code to a local region around said person or group of people, and docking means for downloading said identification code when said portable module is docked; at least one docking station, the or each docking station being adapted to co-operate with said docking means of a said portable module for registering said person or group of people in queue sequence for a respective queue by downloading said identification code from said portable module when docked; a queue manager for maintaining the queue sequence for the or each queue and including first communication means for receiving the or each downloaded code, and a transmitter for transmitting said signals to each portable module to instruct said person or group of people carrying a said portable module to join a queue; at least one module detector for detecting any portable modules in the vicinity of the or each queue; at least one module detector for detecting any transmitted identification codes, a said module detector being arranged at the location of the or each queue to detect when the person or group of people carrying said portable module joins the queue; and second communication means arranged between said queue manager and the or each module detector to communicate any detected identification codes to said queue manager; said queue manager being adapted to update the or each queue sequence using the or each detected identification code and the or each downloaded identification code to remove the or each detected identification code from the front of the respective queue sequence and to add the or each downloaded identification code to the back of the respective queue sequence.

The present invention can thus provide a queue management system which allows people who wish to queue to be free to undertake other activities. The time involved in physically queuing can be drastically reduced to perhaps a few minutes. The system maintains the place of users in each queue and informs them when they should physically join the queue.

Conveniently, the method of communicating between the portable modules and the queue manager is by way of radio paging messages which can be received and displayed by the portable modules.

Although conveniently the indication by the indicator means can be passed to the user visually, e.g. by a display, the indications could be audible, e.g. a spoken message or a tone.

The present invention also can provide information on the whereabouts of the users of the system which can, in some applications, provide very useful management information. In order to facilitate this, in accordance with one embodiment of the present invention the system includes at least one additional module detector provided at locations away from the or each queue for detecting any portable modules in the vicinity of the or each additional module detector by detecting any transmitted identification codes, the or each additional module detector being connected to the queue manager by the second communication means and the queue manager being adapted to use any detected identification codes to track the locations of each person or groups of people carrying a portable module.

In order for the system to be able to distinguish whether a user is merely in the vicinity of a queue or has actually joined a queue, preferably the or each module detector includes a pair of detecting antennae arranged as a gate through which a person or group of people carrying a portable module will pass to join a queue. In this arrangement either the queue manager or the or each module detector includes correlation means to correlate signals for any detected identification codes from the pair of detecting antennae to determine whether a portable module has passed therethrough and if so to pass the detected identification code to the second communication means.

In this way the module detectors can identify whether the user is merely in the vicinity or has actually joined the queue. If the user is merely in the vicinity, the second communication means passes the detected identification codes flagged as representing portable modules being only in the vicinity of the module detector. Alternatively, the identification codes detected by the pair of detecting antennae are passed by the second communication means to the queue manager where the correlation is carried out to determine whether a user has passed through or merely by the pair of antennae.

In one embodiment the transmitter means of each portable module is adapted to periodically transmit the identification code stored in its memory means.

In an alternative embodiment the or each module detector includes a prompting transmitter for transmitting a prompting signal over a short range to cause any portable modules in range to respond by transmitting their identification codes, each portable module including prompt receiving means for receiving the prompting signal and the transmitter means of each portable module being responsive to the received prompting signal to transmit the identification code stored in its memory means.

Thus, when a portable module comes within range of a module detector, its transmitted identification code will be received by the module detector and passed on to the queue manager. In order to avoid conflicts between transmissions from more than one portable module at the same frequency at the same time, interference can be avoided by delaying the transmission of the identification code for a random or pseudo-random delay period. Alternatively, some of the portable modules can transmit the identification codes at different frequencies or each portable module transmitting at the same frequency could transmit the identification code after a unique delay period.

In one embodiment the or each module detector transmits a unique prompting signal and the portable modules include identification means to compare the unique prompting signal with a stored prompting signal corresponding to a respective queue to determine whether the person or group of people are at the correct queue, and means to indicate to the person or group of people whether or not the person or group of people are located in the correct queue.

When the system is designed for use in a defined area, e.g. theme park which has exits, the system preferably includes at least one module detector at each exit to detect portable modules to prevent the portable modules being removed from the defined area.

This prevents the loss of the portable modules by deliberate or accidental removal from the defined area.

Preferably the or each docking station includes queue display means for displaying a selection of queues which the person or group of people may wish to join, input means to allow the person or group of people to select which queue they wish to join and downloading means for downloading the identification code of the docked portable module, for passing the downloaded identification code to the queue manager via the first communication means, and for passing the identity of the or each queue which the person or group of people wish to join to the queue manager via the first communication means. The queue manager is adapted to register the person or group of people in at least one queue sequence dependent upon the downloaded identification code and the received queue identity.

In an alternative embodiment, a person can remotely register for a plurality of queues using a remote input arrangement, e.g. a display and keys.

Such an arrangement could for instance be provided at the user's hotel. When a user registers in this way a portable module identification code (or the portable module itself) is assigned to that user. The user can then either pick up the assigned module later or by for example using a password, select a portable module and have the assigned identification code uploaded to the portable module when the portable is docked. For this facility a means of identifying such a user is required. This can take the form of a password for example which can be given to an attendant to receive the assigned portable module or it can be input to the docking station when a portable module is docked to cause the queue manager to upload the assigned identification code.

In order for the queue manager to receive data on the person or group of people who are using the portable module, the display means and the input means of the or each docking station are preferably adapted to respectively display requests for data on the person or group of people and to allow the input of such data for transmission to the queue manager via the first communication means.

The docking station conveniently allows the person or group of people to select a preferred sequence of queues to be joined and preferred times of joining the queues and allows the reselection of the preferred sequence and the preferred times at a later time.

For multiple queues, the queue manager optimises the position of a person or group of people in each of the queue sequences to allow the person or group of people to join each queue and attend each event being queued for. In order to do this, the queue manager preferably includes queue information storage means to store information on the predicted rate at which the or each queue will move and the actual rate of queue movement and the queue manager is adapted to use the stored information to optimise the length of the or each queue sequence and to enable the optimisation of the sequence of queues. Once the queue manager has determined the optimum queue sequence, it transmits data on the queue sequence and times at which the queue should be joined to the portable modules and this data is stored in the memory means of each portable module for display.

In order to avoid the necessity for transmitting a large number of messages to each portable module, in accordance with one embodiment of the present invention each portable module includes a message memory for storing a plurality of standard messages.

The queue manager is adapted to send a desired message activation signal to the selected portable modules whereupon the selected portable modules display a desired message from the stored plurality of messages on the display in response to the activation signal.

In one embodiment the queue manager is able to send a control signal to selected said portable modules whereupon the selected portable modules respond by switching the mode of operation to revert to a normal pager messaging mode.

In one embodiment, when a user registers for a queue sequence, the time of registration is logged by the queue manager. The queue manager is able to transmit messages to each of the portable modules which have been registered within a certain time window. This feature is useful where managers of a theme park wish to allow its users only a limited number of hours of access to the park or to certain activities. A message can be sent to the users which registered within a time window. This allows a transmission of a time-out message transmitted to the users which are registered within a time window to indicate that they no longer have access to the park or to certain activities and should leave.

In the present invention when a portable module indicates that the user should join a queue, there is no guarantee that the user will respond by joining the correct queue at the correct time. Therefore, in order to ensure that the multiple queue sequencing runs smoothly, the present invention preferably includes an access control mechanism associated with the or each module detector to allow access to a queue area for a queue and the queue manager is adapted to compare an detected identification code with the identification codes of the queue sequence associated with the queue to determine if the detected identification code falls within a predetermined range of the front of the queue sequence, and to transmit an access denied signal over the second communication means to the access control mechanism if the detected identification code is determined to be outside the predetermined range. The access control mechanism is then responsive to the access denied signal to prevent a person or a group of people carrying the portable module associated with the detected identification code from gaining access to the queue area.

Preferably the queue manager is adapted to transmit an explanatory message to the portable module which has been denied access to the queue area to explain the reason why access has been denied.

Alternatively, each portable module is adapted to store a default acceptance time window associated with each queue for which the identification code of the portable module has been entered in the queue sequence reason messages, a portable module which has been denied access being adapted to identify the pair of antennae to determine whether the portable module is at the correct queue area at the correct time, and to select and display an appropriate reason message to explain why access has been denied.

In one embodiment a plurality of portable modules can be assigned as a group and each member of a group of portable modules has an identification code which identifies which group the portable modules belong to.

The or each docking station is adapted to allow the selection of the option for the members of a group of people to allow them to each have a portable module.

For members of a group, when one member places the portable module in the docking station, it is possible for that member to input a group specific message which is sent by the queue manager to all members of the group. It is also possible for the group member to request information on the locations of the group members. The queue manager is able to provide such information which is then displayed at the docking station to allow the group member to locate other members of the group.

Since the queue manager is able to monitor the location of the portable modules, it is possible for the queue manager to send area specific messages to portable modules which are known to be in a specific area. Such messages can for instance be prompting advertisements for local attractions or information on local facilities.

When the portable module is docked in the docking station, it is possible for a user to select the language of the messages to be displayed by the portable unit. Also, the queue manager is able to set the messages which are stored in the message memory and the frequency of operation of the transmitter within the portable module. Further, the queue manager can download the default acceptance time window, e.g. +5 mins, -10 mins.

In one preferred embodiment the present invention can also provide a plurality of portable tagging modules, each portable tagging module being arranged to be carried by a person or a group of people to be tracked. Each portable module comprises memory means for containing the unique identification code, transmitter means for transmitting the identification code over a short range to confine the transmitted identification code to a local region around the person or group of people carrying the portable tagging module, and docking means for docking with the or each docking station for downloading the identification code to the queue manager. The or each docking station is adapted to allow a person or group of people carrying a portable module to associate at least one portable tagging module with the portable module. A docking station can prompt the selection of a tagging option when the portable module is docked to download the identification code thereof and to subsequently request the docking of a portable tagging module to download the identification code thereof.

The queue manager is then responsive to the downloaded identification codes to associate the identification codes. The or each docking station is further able to transmit a location request signal for associated identification code of a portable module or tagging module when a portable module or portable tagging module is docked. The queue manager responds to the location request signal to transmit information on the location of the associated portable module or portable tagging module to the docking station for display thereby.

Where there are fees associated with one or more queues, in accordance with one embodiment the or each docking station includes payment means for receiving payment in respect of a queue which has a fee associated therewith. The payment means is adapted to request payment and await receipt of payment before registering a person or group of people in a queue sequence for a desired queue which has a fee associated therewith.

In an alternative embodiment of the present invention near each docking station includes payment means for receiving payment to be credited to the person or group of people carrying a portable module and the payment is associated with the identification code of the portable module. The queue manager includes credit storing means for receiving and storing information on the payment to be credited to a portable module from the docking station, queue cost information memory means containing information on the cost of the or each queue which has a fee associated therewith, and

debiting means for debiting funds from the credit stored in the credit storing means when the queue manager receives a downloaded identification code from the module detector at a queue which has a fee associated therewith. The queue manager is adapted to transmit information on stored credit in the credit storing means through a portable module to that portable module for display to allow the user to determine how much credit he has left.

In the above alternative embodiments the payment means can conveniently comprise a credit card reader.

It can thus be seen from the above that the system can conveniently comprise a combined short range pager unit and electronic tag, gate units and a base station including a controlling computer.

In the present invention the queue sequence comprises a virtual queue which conveniently resides in a computer system's memory and holds a user's place in the queue in the same order as if he had remained physically present.

Embodiments of the present invention will now be described with reference to the accompanying drawings, in which:

Figure 1 is a schematic drawing of the basic elements of the system in accordance with one embodiment of the present invention;

Figure 2 is a schematic diagram of the system in operation in a theme park in accordance with one embodiment of the present invention;

Figure 3 illustrates the display of the portable module;

Figure 4 is a block diagram of the portable module;

Figure 5 is a diagram of the portable module illustrating the one line scrolling display;

Figure 6 is a schematic illustration of a docking station;

Figure 7 is a schematic diagram of a typical ride queuing area; and

Figure 8 illustrates a gate unit in accordance with one embodiment of the present invention.

Referring now to the drawings, as can be seen in

Figure 1 the system comprises a portable module comprising a combined short range pager unit and electronic tag, gate units 2 and a base station comprising a controlling computer 3 and a transmitter 4. The controlling computer 3 is linked to the transmitter 4 by a communication line 5 to allow the transmission of messages to the portable module 1.

The controlling computer 3 is also linked to the gate units 2 by a further communication line 6 to receive downloaded identification codes which have been detected by the gate unit 2 from the portable unit 1.

Figure 2 illustrates the arrangement of one embodiment of the present invention used in a theme park. As can be seen in Figure 2, a central computer 3 receives downloaded identification codes from a plurality of gate units 2 positioned at various rides in the park. Also, the controlling computer 3 receives downloaded identification codes from additional module detectors 7 positioned throughout the park to enable the position of portable modules to be determined.

In a theme park there is also provided a docking station 8 within an information kiosk 9. As people enter the theme park via the entrance, they can go to the information kiosk 9, take a portable module 1 from a rack and insert it in a docking station 8.

Figure 6 illustrates the display which will allow the user to select the queues to be joined. In Figure 6 the portable module has been termed a "prompter".

When the prompter is docked in the docking station its identification code is downloaded and sent via the communication line 10 to the controlling computer 3.

Also, the queues (or rides) which the user has registered for will be sent to the controlling computer 3 together with the preferred times and preferred sequence of rides to enable the controlling computer to determine the optimum sequence and time of the rides. Once the sequence of rides has been entered and the prompter removed from the docking station, the controlling computer 3 will transmit messages to each of the prompters 1 indicating the sequence and times of the rides. Such a message is illustrated in the illustration of the prompter in

Figure 3. Figure 5 illustrates an alternative display arrangement which allows for the display to scroll across to indicate the ride or attraction, the number of places reserved in the queue and the time at which the physical queue should be joined.

Thus having registered in the "virtual" queue for a number of rides, the user is free to utilise time which would normally be taken up by queuing by visiting other attractions in the park. When it is time to join a physical ride queue, the user will pass through or by the ride gates 2 which will detect the presence of the prompter 1 by receiving its identification code. This identification code is then downloaded to the controlling computer 3.

Thus the prompter comprises a combined short range pager unit and electronic tag which is capable of receiving messages from the central computer 3 via the transmitter 4 at the base station by techniques used in commercially available "on site pagers". The prompter 1 includes an electronic tagging system and a memory containing a unique serial number to identify the particular prompter and hence its associated user.

The prompter unit is capable of transmitting the serial number when required to be detected by the module detectors 2. The transmitter can be of any conventional type such as that used in automobile remote locking or security systems. This transmitter can be arranged either to transmit the identification signal periodically or only in response to a prompting signal from the gate units 2.

Figure 4 is a block diagram of the portable module 1 of the present invention. A receiver 20 receives paging messages in the form of codes to cause the display of messages on the display 30. A microprocessor 40 is provided to decipher the receiver codes and the microprocessor 40 has a memory 50 and switch 60 associated therewith. The portable module also has a receiver 70 for receiving the "identify yourself" signals from the gate units 2 and the module detector 7. The microprocessor 40 is responsive to the "identify yourself" signal to record the transmission of the portable module's serial number via the transmitter 80.

The portable unit is able to display the ride sequence and times. The display can conveniently be an alphanumeric display. A simplified prompter can be provided without such an alphanumeric display with a simpler ride indication arrangement for applications which do not require readable messages.

Registration for queues by users can be received either automatically by the removal of a prompter from a dispenser for a single ride or for multiple rides the user will be required to enter manually the required rides and ride sequence following the instructions on the display as shown in Figure 6.

Normally groups would work with a single prompter for the whole group, but it is possible for individual members of a group to each be provided with a prompter. This is an option which can be made available at the docking station whereby a group of prompter can be assigned to be associated as a group whereby their identification numbers which are downloaded to the controlling computer are marked as being associated with a group.

The identification codes of prompters can either be preloaded or downloaded from the controlling computer when the prompter is docked. Other information and commands can also be downloaded from the controlling computer, e.g. the transmission frequency of the transmitter of each prompter. Also, the language or the messages to be displayed on the display of the prompter can be selected by a user at this stage.

Thus for activities involving multiple queues, the controlling computer can accept time and sequence preferences from the user during registration. The user also has the facility to reset his sequence and time preferences at any time after registration.

The controlling computer 3 will, after registration, transmit activation codes to initiate the display of messages to advise the user when they should join a physical line, or to display other standard messages. A suite of standard messages, each enabled by its activation code, is stored in read-only memory (ROM) in the prompter to increase the number of messages that can be transmitted in the required update time. Other activation codes can produce specific modes of operation in the prompter. One particular code will enable a specific prompter to revert to a normal pager messaging mode for applications where this option is included.

The queue manager consists of a number of modules with clearly defined interfaces. Reliability through redundancy is achieved by having a duplicate computer system which operates the same software and is input with the same data. The modules are:

User Database - record structure

Record Entry

Record Selection

Record Update

Queue Database - list of prompters queuing for each feature

Select Information from User Database
 Add or Remove Records
 Calculate Attendance Times and Route
 Determine Optimum Queue Sequence(s)
 Calculate or Accept User Attendance Time Windows
 Transmission - messages to be sent by the base station to the prompters
 Format Messages
 Sequence Messages
 Interface to Transmitter
 Interfaces - drivers/format for communication other than transmission above
 Input Terminals
 Accept Preference Information
 Download to Prompters (serial number,
 frequency features as appropriate)
 Gate Units
 Correlate Signals at ride entrances
 Standard packages and interfaces are used wherever possible.

The gate units 2 include circuitry to at least passively listen for the transmitted identification codes and preferably include circuitry to transmit the prompting signal. The gate units will be set up at the entrance to the physical queue to control access to the queue area. The signals from such gate units can have an identification feature built in so that the prompter can recognise if it is at the correct location and provide a message to the user. Such an identification feature can be achieved by for example pulsing the transmitter on and off, modulating the signal, setting the frequency of the signal, or selective polarisation of the signal. When the gate unit 2 detects an identification code this is downloaded to the host computer. If it is determined that the identification code corresponds to an identification code within a predetermined region of the front of the queue sequence held within the memory of the controlling computer 3, the user is permitted access through the gate units. If, on the other hand, the detected identification code is not within a predetermined range on the front of the queue sequence, a signal is transmitted by the host computer to the queue area to deny the user access to the queue area. The controlling computer 3 also transmits a message to the prompter to give a reason as to why access has been denied. Access could be denied because the user has arrived either before or after the time, is at the wrong ride or the user is at the wrong ride and at the wrong time.

Throughout the park area module detecting units 7 are provided simply to collect detected identification codes of prompter in the vicinity. These detected identification codes are downloaded to the controlling computer 3 to enable the controlling computer 3 to monitor the location of the prompter 1 within the park.

In large systems there is a likelihood of interference between transmitted identification codes of prompter in the locality of the gate units 2 or the module detectors 7. There are a number of ways in which this problem of interference can be reduced or avoided. The queue control infrastructure and gate unit positioning can be appropriately designed in order to provide sufficient separation between prompters, e.g. by using turnstiles, barriers and the like. Also, the power level of the transmitters of the prompters can be reduced and the sensitivity of the receivers of the gate units 2 and the module detectors 7 altered. Further, a random or pseudorandom delay can be introduced into the response time of the transmitters to the prompting signal from the gate units 2 and module detectors 7. Alternatively, different prompters can use different frequencies.

Further, responses from the portable units can be sequenced by the controlling computer sending enabling activation codes such that only a certain proportion of the prompters which share the same transmitter frequency can respond at any one time. Another method of overcoming interference problems is to allow the prompter to transmit its identification code more than once while it is in the vicinity of the gate unit 2 or the module detector 7.

Figure 8 illustrates one arrangement for a gate unit. A receiver is placed either side of a gateway to detect identification codes of prompter carried by users as they pass through the gate. The identification codes detected by the two detectors are correlated to determine whether a prompter is merely in the vicinity or has passed between the detectors.

Figure 7 illustrates a ride queuing area wherein there are provided entrance gates 100 through which users pass. If the users are early, late, or in the wrong queue, the turnstile 101 will deny access into the mixing area 102 which is the end of the short queue 103 for the ride loading area 104. As can be seen in Figure 7, this ride queuing area allows for the park to allow for only some users to use the

portable units. Park users without portable units will have to join the conventional long queue 105.

Thus installation of the queue management system should maximum ride/show utilisation, ease park management issues, raise spending on secondary attractions and most importantly, greatly increase customer satisfaction. Some modification of the queuing infrastructure in the park is required, and staff could carry portable modules for communication purposes and to give their management information on their location.

The park management benefits will include the following: 1) greater control in crowd movement, 2) increased staff control, 3) information in advance on user movement preferences, 4) the ability to shorten attendance time when required by controlling routing and attraction attendance such that users will be led to exit areas earlier, and 5) automatic supply of information for customer research.

The system would require minimal staff assistance to minimise staff increase and, where appropriate infrastructure design, the system is failsafe defaulting to exiting systems in case of a catastrophic fault. The park visitor or user would use terminals installed at park entry points and at information kiosks throughout the park to enter ride and time preferences. The system would request other relevant information such as height or health status, which may be relevant in allowing access to certain rides. In the case of a group of visitors sharing one portable module, information on each individual will be required.

The advantages of embodiments of the present invention are: 1) Easy and attractive audio visual question and answer interfacing to the input terminals at the docking stations by an attractive kiosk design, simple keyboard and a fun, interactive, guide character, 2) A rendezvous aid service for groups using multiple portable modules. A member of a group which has been split up could place his portable module in the docking station at one of the information kiosks and the system could send a message to the portable modules of the rest of his group with a suggested rendezvous point.

3) A lost child/child security device. This could optionally use a smaller unit without the message display facility, where a specific activation code enables the ability to respond to every identify yourself message from every gate unit.

An option is to have an even smaller unit without any pager receiver circuitry which would operate continuously, responding to every identify yourself message from every gate unit.

4) Zone specific messages promoting other utilised attractions, other promotional messages and competitions.

5) Where separate attractions have separate tickets, the portable module could act as an electronic ticket. Registration could be coupled with automatic payment by a credit card reader in the docking station.

6) Theft or accidental removal of the portable module from the park could be controlled by having a gate unit at each of the park exits.

7) Portable modules which display in multiple languages can be offered as an option.

Whilst it is expected that all users or user groups would carry prompters, partial usage would be possible as a premium service with an increase in the standard fee.

The controlling computer 3 can store information in a database on each user and each member of a group, e.g. preferred language, attractive preferences, time preferences, calculated optimum route, the number in the group, attraction restriction information by individual user, other relevant information on the user, e.g. any relevant disability, baby being carried, stroller present etc., optional services activated (which might require additional user information), and credit available (where applications where individual ride tickets are used and the portable modules acts an electronic ticket).

The controlling computer 3 can operate to include a procedure which can ensure that a user registering late in the day would be given access to the same number of queues as a user registering earlier in the day. Such a user could join certain queues near the front. The structuring and managing of the queues are features which can be customised to suite a particular situation. The controlling computer 3 will thus operate in accordance with the customised algorithm to manage the queues.

The controlling computer 3 can be programmed to re-allocate every user's sequence used in accordance with a preset algorithm or to cope with unexpected events. In order to warn the user of this possibility, when the user registers and is shown a route to the queues, and the queue sequence, an explanation of this possibility will need to be presented to the user.

Three examples of situations which could result in the re-allocation of every user's sequence are 1)
The theme park is lightly loaded and certain rides are to be closed down. The late users may not physically be able to get from one ride to another in time without some re-arrangement of queues, even though slots are available.

2) It may be policy that every user gets a minimum number of rides (depending on the time registration). If the weather meant that a park was lightly loaded in the morning but full in the afternoon, the morning attendees may have had a large number of rides. These morning attendees could then be given a reduced number of rides in the afternoon to allow an increased number of rides to the late attendees.

3) If ride failure occurs it may be fairer to reallocate all the queues.

As described hereinabove, the portable module of the present invention can utilise conventional paging message techniques.

The POCSAG protocol is one of a number of messaging protocols used in paging. Any protocol can be modified in a similar way to provide the activation of pre-stored messages. The framing structure is as follows

Preamble 1.125 sec Batch 1 1.0625 sec Batch 2 1.0625 sec Batch
sec

Each Batch = 17 code words

A Svc code word plus 8 frames of two code words

sync Frame

Code word 1 2 - 29 address bits 20,21 22 - 31 coding bits 32

1 - Message Tag (0- address word, 1- message word)

20, 21 - Function Bits

32 - Even parity

Possible activation codes are shown in the table below and these are such that one frame is

.../desc?LG=en&CY=gb&DB=EPD&PNP=GB2307324&PN=GB2307324&FTDB=@RTDF 29/10/02

needed to define a command or initiate a pre-stored message, except when special features such as the text messaging mode is used.

The standard structure could be modified as follows:

1 - 14 address bits 15 16 - 31 Message/Command Coding bits 3

15 Set Mode

32 Even parity

Prompters store and display two messages, one each for the next and subsequent attraction.

The second message is sent every 5th time slot, the first message every other.

Messages and commands are shown in the next two tables

Special Mode and Programming Commands cannot be transmitted by the base station. They are only used when prompter is in a kiosk docking station, or at the maintenance base for programming.

The Standard messages, with various language versions if required, are stored in memory in the prompter.

In the POCAG protocol it is possible to refresh the messages of more than 4,000 portable modules every three minutes. If different pager frequencies are used, the number of portable modules from which the messages can be refreshed in three minutes increases by the number of frequencies used. Thus, this arrangement can provide for a large number of users in a multiple queue environment.

Although the present invention has been described hereinabove with reference to specific embodiments, the present invention is not so limited and modifications smaller than the scope of the claims will be clear to a skilled person in the art.

Data supplied from the esp@cenet database - 12

Claims

CLAIMS

1. A queue management system for managing at least one queue of people, the system comprising a plurality of portable modules, each portable module being arranged to be carried by a person or a group of people and including ~~memory means for containing a unique identification code~~, indicator means for indicating to said person or group of people when it is time to join the or each queue, signal receiver means for receiving signals to cause said indicator means to be operative, transmitter means for transmitting said identification code over a short range to confine the transmitted identification code to a local region around said person or group of people, and ~~docking means for downloading said identification code when said portable module is docked~~;;

at least one docking station, the or each docking station being adapted to co-operate with said docking means of a said portable module for registering said person or group of people in queue sequence for a respective queue by downloading said identification code from said portable module when docked; a queue manager for maintaining the queue sequence for the or each queue and including first communication means for receiving the or each downloaded code, and a transmitter for transmitting said signals to each portable module to instruct said person or group of people carrying a said portable module to join a queue; at least one module detector for detecting any portable modules in the vicinity of the or each module detector by detecting any transmitted identification codes, a said module detector being arranged at the location of the or each queue to detect when the person or group of people carrying said portable module joins the queue; and second communication means arranged between said queue manager and the or each module detector to communicate any detected identification codes to said queue manager; said queue manager being adapted to update the or each queue sequence using the or each detected identification code and the or each downloaded identification code to remove the or each detected identification code from the front of the respective queue sequence and to add the or each downloaded identification code to the back of the respective queue sequence.

2. A queue management system as claimed in Claim 1, wherein said transmitter of said queue manager is adapted to transmit radio paging messages to each portable module, and said signal receiver means of each portable module is adapted to receive said radio paging messages.

3. A queue management system as claimed in Claim 1 or Claim 2, including at least one additional module detector provided at locations away from the or each queue for detecting any portable modules in the vicinity of the or each additional module detector by detecting any transmitted identification codes, the or each additional module detector being connected to said queue manager by said second communication means, and said queue manager being adapted to use any identification codes detected by the or each module detector and the or each additional module detector to track the locations of each person or group of people carrying a said portable module.

4. A queue management system as claimed in any preceding claim, wherein the or each module detector includes a pair of detecting antennae arranged as a gate through which a person or group of people carrying a said portable module will pass to join a queue, the or each module detector including correlation means to correlate signals for any detected identification code from said pair of detecting antennae to determine whether a said portable module has passed therethrough and if so to pass the detected identification code to said second communication means.

5. A queue management system as claimed in Claim 4, wherein the or each module detector includes means to pass to said second communication means any detected identification codes flagged as representing portable modules being only in the vicinity of said module detector if said correlation means determines that the portable modules have not passed through said pair of detecting antennae.

6. A queue management system as claimed in any preceding claims, wherein said transmitter means of each portable module is adapted to periodically transmit the identification code stored in said memory means.

7. A queue management system as claimed in any one of Claims 1 to 5, wherein the or each module detector includes a prompting transmitter for transmitting a prompting signal over a short range to cause any portable modules in range to respond by transmitting their identification codes, each portable module including prompt receiving means for receiving said prompting signal, said transmitter

means of each portable module being responsive to the received prompting signal to transmit the identification code stored in said memory means.

8. A queue management system as claimed in Claim 7, wherein said transmitter means of each portable module is adapted to transmit said identification code after a random or pseudo-random delay after said prompt receiving means receives said prompting signal.

9. A queue management system as claimed in any one of Claims 6, 7 or 8, wherein said transmitter means of at least some of said portable module transmit said identification codes at different frequencies.

10. A queue management system as claimed in Claim 8 or Claim 9, wherein said prompting transmitter of the or each module detector transmits an identifying prompting signal, and said portable module includes identification means to compare said identifying prompting signal with a stored prompting signal corresponding to a respective queue to determine whether the person or group of people are at the correct queue, and means to indicate to the person or group of people whether or not the person or group of people are located in the correct queue.

11. A queue management system as claimed in any preceding claim for use in a defined area having at least one exit for the people or groups of people carrying said portable modules, the system indicating at least one said module detector at each exit to detect portable modules to prevent the portable modules being removed from said defined area.

12. A queue management system as claimed in any preceding claim, wherein said queue manager is adapted to load as identification code into said memory means of a said portable module using said first communication means when said portable module is docked in a said docking station to register said person or group of people in a queue sequence.

13. A queue management system as claimed in any one of Claims 1 to 11, wherein the identification code is preloaded in said memory means of each portable module.

14. A queue management system as claimed in any preceding claim wherein the or each docking station includes queue display means for displaying a selection of queues which the person or group of people may wish to join; input means to allow the person or group of people to select which queue they wish to join; and downloading means for downloading the identification code of the docked portable module and passing the downloaded identification code to said queue manager via said first communication means, and for passing the identity of the or each queue which the person or group of people wish to join to said queue manager via said first communication means; said queue manager being adapted to register the person or group of people in at least one said queue sequence dependent upon the downloaded identification code and the received queue identity.

15. A queue management system as claimed in Claim 14, wherein said display means and said input means of the or each docking station are adapted to respectively display requests for data on the person or group of people and to allow the input of such data for transmission to said queue manager via said first communication means.

16. A queue management system as claimed in any preceding claim wherein said indicator means of each portable module comprises a display to display messages indicative of the queues for which the person or group of people is registered to join and the time at which the queues should be joined.

17. A queue management system as claimed in Claim 16 wherein said docking station is adapted to allow the person or group of people to select a preferred sequence of queues to be joined and preferred times of joining the queue, and to reselect said preferred sequence and said preferred times.

18. A queue management system as claimed in Claim 16 or Claim 17 wherein said queue manager is adapted to optimise the position of a person or group of people in each of a plurality of queue sequences to allow the person or group of people to join each queue and attend each event being queued for.

19. A queue management system as claimed in Claim 18, wherein said queue manager includes queue information storage means to store information on the predicted rate at which the or each queue will move and/or the actual rate at which the queue is moving, said queue manager being adapted to use said stored information to optimise the length of the or each queue sequence and to enable the optimisation of the sequence of queues.

20. A queue management system as claimed in any one of Claims 16 to 19, wherein said queue manager is adapted to control said transmitter to transmit data on the queue sequence and times at which the queues should be joined, and said memory means of each portable module is adapted to store said data.

21. A queue management system as claimed in any one of Claims 16 to 20, wherein each portable module includes a message memory for storing a plurality of standard messages, said queue manager being adapted to send a desired message activation signal to selected said portable modules using said transmitter, and said selected portable modules being adapted to display a desired message from said stored plurality of messages on said display in response to said activation signals.

22. A queue management system as claimed in any one of Claims 16 to 22, wherein said queue manager is adapted to send a control signal to selected said portable modules, said selected signal to switch mode of operation to operate as a radio pager.

23. A queue management system as claimed in any one of Claims 16 to 22, including an access control mechanism associated with the or each module detector to allow access to a queue area for a queue, said queue manager being adapted to compare a detected identification code with the identification codes of the queue sequence associated with the queue to determine if said detected identification code falls within a predetermined range of the front of the queue sequence, and to transmit an access denied signal over said second communication means to said access control mechanism if said detected identification code is determined to be outside said predetermined range, said access control mechanism being responsive to said access denied signal to prevent the person or group of people carrying the portable module associated with the detected identification code from gaining access to the queue area.

24. A queue management system as claimed in Claim 23, wherein said queue manager is adapted to transmit an explanatory message signal to the portable module which has been denied access to the queue area to explain the reason why access has been denied.

25. A queue management system as claimed in Claims 23, wherein said each portable module is adapted to store a default acceptance time window associated with each queue for which the identification code of the portable module has been entered in the queue sequence reason messages, a portable module which has been denied access being adapted to identify the pair of antennae to determine whether the portable module is at the correct queue area at the correct time, and to select and display an appropriate reason message to explain why access has been denied.

26. A queue management system as claimed in any one of Claims 16 to 25, wherein a plurality of said portable modules can be assigned as a group, each member of a group of portable modules having an identification code which identifies which group the portable module belongs to, the or each docking station being adapted to allow the selection of the option for the members of a group of people to each have a portable module.

27. A queue management system as claimed in Claim 26, wherein said docking station is adapted to allow a member of a group to input a group specific message to said queue manager via said first communication means when the member's portable module is docked, said queue manager being responsive to said group specific message to transmit a message to all members of the group.

28. A queue management system as claimed in Claim 26 or Claim 27, wherein said queue manager is adapted to monitor the locations of said portable modules, the or each docking station including means to input a location request to request the location of the group members when a group member's portable module is docked, said queue manager being responsive to said location request to transmit information on the location of the group members for display by the docking station.

29. A queue management system as claimed in any one of Claims 16 to 28, wherein said queue manager is adapted to monitor the locations of said portable modules and to send area specific messages to portable modules known to be in at least one specific area.

30. A queue management system as claimed in any one of Claims 16 to 29, wherein said queue manager is adapted to program the language of the messages displayed on said display of a said portable module when said portable module is docked.

31. A queue management system as claimed in Claim 21, wherein said queue manager is adapted to send the messages stored in said message memory of a said portable module when said portable module is docked.

32. A queue management system as claimed in any preceding claim, wherein said queue manager is adapted to set the frequency of said transmitter of a said portable module when said portable module is docked.
33. A queue management system as claimed in any preceding claim including a plurality of portable tagging modules, each portable tagging module being arranged to be carried by a person or group of people to be tracked, comprising memory means for containing a unique identification code, transmitter means for transmitting said identification code over a short range to confine the transmitted identification code to a local region around the person or group of people carrying the portable tagging module, and docking means for docking with the or each docking station for downloading said identification code to said queue manager; the or each docking station being adapted to allow a person or group of people carrying a said portable module to associate at least one said portable tagging module with said portable module, said docking station having means for prompting the selection of a tagging option when said portable module is docked to download the identification code thereof, said means for prompting subsequently requesting the docking of a said portable tagging module to download the identification code thereof; said queue manager being responsive to said means for prompting and said downloaded identification codes to associate said identification codes; the or each docking station including means to transmit a location request signal for an associated identification code of a portable module or portable tagging module when a portable module or portable tagging module is docked; said queue manager being responsive to said location request signal to transmit information on the location of the associated portable module or portable tagging module to said docking station for display thereby.
34. A queue management systems as claimed in any preceding claim, wherein each portable tagging module includes a receiver for receiving prompting signals from the or each module detector, said transmitter of each portable tagging module being responsive to said prompting signals to transmit said identification code.
35. A queue management system as claimed in any preceding claim, wherein the or each docking station includes payment means for receiving payment in respect of a queue which has a fee associated therewith, said payment means being adapted to request payment and await receipt of payment before registering a person or group of people in a queue sequence for a desired queue which has a fee associated therewith.
36. A queue management system as claimed in any one of Claims 1 to 34, wherein the or each docking station payment means for receiving payment to be credited to the person or group of people carrying a said portable module and to be associated with the identification code of said portable module; said queue manager including credit storing means for receiving and storing information on the payment to be credited to a portable module from said docking station, queue cost information memory containing information on the cost of the or each queue which has a fee associated therewith, debiting means for debiting funds from the credit stored in said credit storing means for a portable module when said queue manager receives a detected identification code from said module detector at a queue which has a fee associated therewith; said queue manager being further adapted to transmit information on the credit stored in said credit storing means for a portable module to said portable module for display thereby.
37. A queue management system as claimed in Claim 35 or Claim 36, wherein said payment means comprises a credit card reader.
38. A queue management system substantially as hereinbefore described with reference to and as illustrated in any of the drawings.
